Abstract

This vignette introduces the use of the Bioconductor package DSS (Dispersion Shrinkage for Sequencing data), which is designed for differential analysis based on high-throughput sequencing data. It performs differential expression analyses for RNA-seq, and differential methylation analyses for bisulfite sequencing (BS-seq) data. The core of DSS is a new procedure to estimate and shrink gene- or CpG site-specific dispersions, then conduct Wald tests for differential expression/methylation. Compared with existing methods, DSS provides excellent statistical and computational performance.

Introduction 1

Recent advances in high-throughput sequencing technology have revolutionized genomic research. For example, RNAseq is a new technology for measuring the abundance of RNA products. Compared to gene expression microarrays, it provides a better dynamic range and lower signal-to-noise ratio. Bisulfite sequencing (BS-seq) is a new technology for measuring DNA methylation. Compared to capture-based methods such as MeDIP-seq, it provides single-base resolution and eliminates biases associated with CpG density.

Fundamental questions for RNA-seq or BS-seq data analyses are whether gene expression regulation or DNA methylation dynamics vary under different biological contexts. Identifying sites or regions exhibiting differential expression (DE) or differential methylation (DM) are thus key tasks in functional genomics research.

RNA- or BS-seq experiments typically have a limited number of biological replicates due to cost constraints. This can lead to unstable estimation of within group variance, and subsequently undesirable results from hypothesis testing. Variance shrinkage methods have been widely used in DE analyses based on microarray data. The methods are typically based on a Bayesian hierarchical model, with a prior imposed on the gene-specific variances to provide a basis for information sharing across all genes/CpG sites. In these models, shrinkage is achieved for variance estimation. Using shrunk variance in hypothesis tests has been shown to provide better results.

A distinct feature of RNA-seq or BS-seq data is that the measurements are in the form of counts. These data are often assumed to be from the Poisson (for RNA-seq) or Binomial (for BS-seq) distributions. Unlike continuous distributions such as the Gaussian distribution, the variances depend on means in these discrete distributions. This implies that the sample variances do not account for biological variation between replicates, and shrinkage cannot be applied on variances directly.

In contrast, we assume that our count data come from the Gamma-Poisson (RNA-seq) or Beta-Binomial (BS-seq) distribution. These distributions can be parameterized by a mean and an over dispersion parameter. The over dispersion parameters, which represent the biological variation for replicates within a treatment group, play a central role in the differential analyses.

Here we present a new DE/DM detection algorithm, where shrinkage is performed on the dispersion parameters. We first impose a log-normal prior on the dispersions, and then combine data from all genes/CpG sites to shrink dispersions through a penalized likelihood approach. Finally, we construct Wald tests to test each gene/site for differential expression/methylation. Our results show that the new method provides excellent performance compared to existing methods, especially when the overall dispersion level is high or the number of replicates is small.

For details of the hierarchical model, the shrinkage method and test procedure, please read [2] for differential expression from RNA-seq, and [1] for differential methylation from BS-seq.

2 Using DSS for differential expression analysis

2.1 Single factor experiment

Required inputs for DSS are (1) gene expression values as a matrix of integers, rows are for genes and columns are for samples; and (2) a vector representing experimental designs. The length of the design vector must match the number of columns of input counts. Optionally, normalization factors or additional annotation for genes can be supplied.

The basic data container in the package is SeqCountSet class, which is directly inherited from ExpressionSet class defined in Biobase. An object of the class contains all necessary information for a DE analysis: gene expression values, experimental designs, and additional annotations.

A typical DE analysis contains the following simple steps.

- 1. Create a SeqCountSet object using newSeqCountSet.
- 2. Estimate normalization factor using estNormFactors.
- 3. Estimate and shrink gene-wise dispersion using estDispersion
- 4. Two-group comparison using waldTest.

The usage of DSS is demonstrated in the simple simulation below.

First load in the library, and make a SeqCountSet object from some counts for 2000 genes and 6 samples.
 > library(DSS)

```
F IIDIAIY(DSS)
```

- > counts1=matrix(rnbinom(300, mu=10, size=10), ncol=3)
- > counts2=matrix(rnbinom(300, mu=50, size=10), ncol=3)
- > X1=cbind(counts1, counts2) ## these are 100 DE genes
- > X2=matrix(rnbinom(11400, mu=10, size=10), ncol=6)
- > X=rbind(X1,X2)
- > designs=c(0,0,0,1,1,1)
- > seqData=newSeqCountSet(X, designs)
- > seqData
- SeqCountSet (storageMode: lockedEnvironment)

```
assayData: 2000 features, 6 samples
```

```
element names: exprs
```

protocolData: none

```
phenoData
```

```
sampleNames: 1 2 ... 6 (6 total)
```

```
varLabels: designs
```

varMetadata: labelDescription

```
featureData: none
```

```
experimentData: use 'experimentData(object)'
```

Annotation:

- 2. Estimate normalization factor.
 - > seqData=estNormFactors(seqData)
- 3. Estimate and shrink gene-wise dispersions
 - > seqData=estDispersion(seqData)
- 4. With the normalization factors and dispersions ready, the two-group comparison can be conducted via a Wald test:
 - > result=waldTest(seqData, 0, 1)

```
> head(result,5)
```

A higher level wrapper function DSS.DE is provided for simple RNA-seq DE analysis in a two-group comparison. User only needs to provide a count matrix and a vector of 0's and 1's representing the design, and get DE test results in one line. A simple example is listed below:

```
> counts = matrix(rpois(600, 10), ncol=6)
> designs = c(0,0,0,1,1,1)
> result = DSS.DE(counts, designs)
> head(result)
```

2.2 Multifactor experiment

DSS provides functionalities for dispersion shrinkage for multifactor experimental designs. Downstream model fitting (through genearlized linear model) and hypothesis testing can be performed using other packages such as edgeR, with the dispersions estimated from DSS.

Below is an example, based a simple simulation, to illustrate the DE analysis of a crossed design.

- 1. First simulate data for a 2x2 crossed experiments. Note the counts are randomly generated.
 - > library(DSS)
 - > library(edgeR)
 - > counts=matrix(rpois(800, 10), ncol=8)
 - > design=data.frame(gender=c(rep("M",4), rep("F",4)), strain=rep(c("WT", "Mutant"),4))
 - > X=model.matrix(~gender+strain, data=design)
- 2. make SeqCountSet, then estimate size factors and dispersion

```
> seqData=newSeqCountSet(counts, as.data.frame(X))
```

```
> seqData=estNormFactors(seqData)
```

- > seqData=estDispersion(seqData)
- 3. Using edgeR's function to do glm model fitting, but plugging in the estimated size factors and dispersion from DSS.

```
> fit.edgeR <- glmFit(counts, X, lib.size=normalizationFactor(seqData),</pre>
```

```
+ dispersion=dispersion(seqData))
```

4. Using edgeR's function to do hypothesis testing on the second parameter of the model (gender).

```
> lrt.edgeR <- glmLRT(glmfit=fit.edgeR, coef=2)</pre>
```

```
> head(lrt.edgeR$table)
```

3 Using DSS for differential methylation analysis

3.1 Overview

To detect differential methylation, statistical tests are conducted at each CpG site, and then the differential methylation loci (DML) or differential methylation regions (DMR) are called based on user specified threshold. A rigorous statistical tests should account for biological variations among replicates and the coverage depth. Most existing methods for DM analysis are based on *ad hoc* methods. For example, using Fisher's exact ignores the biological variations, using t-test on estimated methylation levels ignores the coverage depth. Sometimes arbitrary filtering are recommended: loci with coverages lower than an arbitrary threshold are filtered out.

The DM detection procedure implemented in DSS is based on a rigorous Wald test for beta-binomial distributions. The test statistics depend on the biological variations (captured by dispersion parameter) as well as the coverage depth. An important part of the algorithm is the estimation of dispersion parameter, which is achieved through a shrinkage estimator based on a Bayesian hierarchical model [1].

A great advantage of DSS is that the test can be performed even when there is no biological replicates. That's because by smoothing procedure, the neighboring CpG sites can be viewed as "pseudo-replicates", and the dispersion can still be estimated with reasonable precision.

This package depends on bsseq Bioconductor package, which has neat definition of data structures and many useful utility functions. In order to use the DM detection functionalities, bsseq needs to be pre-installed.

3.2 Input data

For one BS-seq experiments, after sequence alignment and some processing, the BS-seq data are usually summarized into following information for each CG position: chromosome number, genomic coordinate, total number of reads, and number of reads showing methylation. For a sample, this information are saved in a simple text file, with each row representing a CpG site. Below shows an example of a small part of such a file:

chr	pos	N	Х
chr18	3014904	26	2
chr18	3031032	33	12
chr18	3031044	33	13
chr18	3031065	48	24
chr18	3031069	17	4
chr18	3031082	93	37
chr18	3031089	76	25
chr18	3031092	76	28

DML/DMR detection using DSS starts from several such text files. A typical DML detection contains two simple steps. First one conduct DM test at each CpG site, then DML/DMR are called based on the test result and user specified threshold. Below we will use example data distributed with DSS to illustrate these steps.

 Load in library. Read in text files and create an object of BSseq class, which is defined in bsseq Bioconductor package. This step requires bsseq Bioconductor package. BSseq class is defined in that package.

```
> library(DSS)
```

```
> require(bsseq)
> path <- file.path(system.file(package="DSS"), "extdata")
> dat1.1 <- read.table(file.path(path, "cond1_1.txt"), header=TRUE)
> dat1.2 <- read.table(file.path(path, "cond1_2.txt"), header=TRUE)
> dat2.1 <- read.table(file.path(path, "cond2_1.txt"), header=TRUE)
> dat2.2 <- read.table(file.path(path, "cond2_2.txt"), header=TRUE)
> BSobj <- makeBSseqData( list(dat1.1, dat1.2, dat2.1, dat2.2),
+ c("C1","C2", "N1", "N2") )[1:10000,]
> BSobj
An object of type 'BSseq' with
10000 methylation loci
4 samples
```

has not been smoothed

2. Perform statistical test for DML by calling DMLtest function. This function basically performs following steps: (1) estimate mean methylation levels for all CpG site; (2) estimate dispersions at each CpG sites; (3) conduct Wald test. For the first step, there's an option for smoothing or not. Because the methylation levels show strong spatial correlations, smoothing can help obtain better estimates of mean methylation when the CpG sites are dense in the data (such as from the whole-genome BS-seq). However for data with sparse CpG, such as from RRBS or hydroxyl-methylation, smoothing is not recommended.

To perform DML test without smoothing, do:

> dmlTest <- DMLtest(BSobj, group1=c("C1", "C2"), group2=c("N1", "N2"))</pre> Estimating dispersion for each CpG site, this will take a while > head(dmlTest) chrpos m111 mu2 diff diff.se stat phi1 3 chr18 3014904 0.5056818 0.4696970 0.035984848 0.23249555 0.15477650 0.287926584 4 chr18 3031032 0.3400000 0.1590909 0.180909091 0.11782933 1.53534850 0.009589628 5 chr18 3031044 0.3445946 0.3409091 0.003685504 0.13210417 0.02789847 0.011041061 6 chr18 3031065 0.4353448 0.3723404 0.063004402 0.10361769 0.60804676 0.010908903 7 chr18 3031069 0.3000000 0.5370370 -0.237037037 0.13990809 -1.69423398 0.013059144 8 chr18 3031082 0.3506787 0.3950000 -0.044321267 0.07762943 -0.57093380 0.008283076 phi2 fdr pval 3 0.01992909 0.87699752 1.0000000

- 8 0.01352427 0.56804452 1.0000000
- To perform statistical test for DML with smoothing, do:

> dmlTest.sm <- DMLtest(BSobj, group1=c("C1", "C2"), group2=c("N1", "N2"), smoothing=TRUE)
Smoothing, this will take a while ...</pre>

Estimating dispersion for each CpG site, this will take a while ...

There are two options for smoothing: a simple moving average, or the BSmooth method implemented in bsseq package. The BSmooth method produces much smoother curve, which is good for visualization purpose. However, it is very computationally intensive, and the results are not very different from moving average in terms of DMR calling. So we recommend using moving average. Smoothing span is an important parameter in smoothing procedure and have non-trivial impact on DMR calling. We use 500 bp as default, and think that it performs well in real data tests.

- 3. With the test results, one can call DML by using callDML function. The results DMLs are sorted by the significance.
 - > dmls <- callDML(dmlTest, p.threshold=0.001)</pre>
 - > head(dmls)

Alternatively, users can specify a threshold for difference. For example, to detect loci with difference greater than 0.1, do: dmls2 <- callDML(dmlTest, delta=0.1, p.threshold=0.001)</pre> > head(dmls2) > chrpos mu1 mu2 diff diff.se stat phi1 507 chr18 3976129 0.006849315 0.95161290 -0.9447636 0.05519960 -17.11541 0.051293128 508 chr18 3976138 0.006849315 0.95161290 -0.9447636 0.05519960 -17.11541 0.051293128 709 chr18 4431501 0.006944444 0.97368421 -0.9667398 0.05818870 -16.61387 0.052066186 710 chr18 4431511 0.006849315 0.97368421 -0.9668349 0.05812148 -16.63473 0.052003498 789 chr18 4564237 0.918478261 0.02083333 0.8976449 0.05836718 15.37928 0.010057974 863 chr18 4657576 0.987179487 0.06250000 0.9246795 0.05876625 15.73487 0.009968422 phi2 pval fdr postprob.overThreshold 507 0.02531726 0 0 1 508 0.02531726 0 1 0 709 0.07025639 1 0 0 710 0.07025639 0 0 1 789 0.06975075 0 0 1 863 0.07423324 0 0 1

When delta is specified, the function will compute the posterior probability that the difference of the means is greater than delta. So technically speaking, the threshold for p-value here actually refers to the threshold for 1-posterior probability, or the local FDR. Here we use the same parameter name for the sake of the consistence of function syntax.

4. DMR detection is also Based on the DML test results, by calling callDMR function. Regions with many statistically significant CpG sites are identified as DMRs. Some restrictions are provided by users, including the minimum length, minimum number of CpG sites, percentage of CpG site being significant in the region, etc. There are some *post hoc* procedures to merge nearby DMRs into longer ones.

```
> dmrs <- callDMR(dmlTest, p.threshold=0.01)</pre>
```

> head(dmrs)

NULL

Here the DMRs are sorted by "areaStat", which is defined in bsseq as the sum of the test statistics of all CpG sites within the DMR.

Similarly, users can specify a threshold for difference. For example, to detect regions with difference greater than 0.1, do:

> dmrs2 <- callDMR(dmlTest, delta=0.1, p.threshold=0.05)</pre>

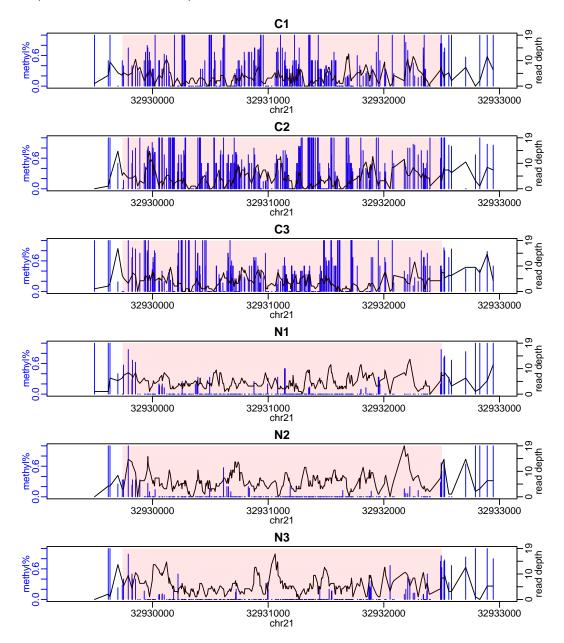

> head(dmrs2)

	chr	start	end	length	nCG	meanMethy1	meanMethy2	diff.Methy	areaStat
22	chr18	5114580	5114712	133	5	0.9921612	0.4121153	0.5800459	18.5069895
160	chr18	19526612	19529997	3386	4	0.5477310	0.2919271	0.2558039	15.3140699
14	chr18	4222533	4222608	76	4	0.7874547	0.3784722	0.4089825	12.3371481
9	chr18	3542620	3542732	113	4	0.7666223	0.7077564	0.0588659	0.9855913

Note that the distribution of test statistics (and p-values) depends on the differences in methylation levels and biological variations, as well as technical factors such as coverage depth. It is very difficulty to select a natural and rigorous threshold for defining DMRs. We recommend users try different thresholds in order to obtain satisfactory results.

- 5. The DMRs can be visualized using showOneDMR function, This function provides more information than the plotRegion function in bsseq. It plots the methylation percentages as well as the coverage depths at each CpG sites, instead of just the smoothed curve. So the coverage depth information will be available in the figure. To use the function, do
 - > showOneDMR(dmrs[1,], BSobj)

The result figure looks like the following. Note that the figure below is not generated from the above example. The example data are from RRBS experiment so the DMRs are much shorter.
